How do you calculate energy price for charging in year N? To simplify the equation, let  $E_{price n}$  be the energy price for charging in year n, described by  $E_{price n} = e_{price} (1 + r)^n$ .

How much will LCOE cost a second set of energy storage investments? This could be a mistake though, because there is no more curtailed solar to charge the devices, which means that the LCOE for the second set of energy storage investments would be \$0.04/kWh plus \$0.06/kWh from charging with existing, dispatchable generators. How can energy storage help electricity users obtain economic benefits?

**Abstract:** As one kind of energy storage (ES) applications, ES can respond to electricity prices and help electricity users obtain economic benefits. In detail, by storing electricity during low price period and releasing power energy during high price period, ES can obtain price arbitrage or lower the energy cost for power consumers. How much does PV cost per kWh? By discounting cycles to a present value of 2.63 million kWh and applying that value, we get an LCOS for this cost component of 2.8 cents per kWh. Applying that value to the annual throughput results in total costs of \$98,674 and PV costs equal to our target of \$74,156. How do you calculate overnight capital costs? As such, the overnight capital costs will be normalized to the amount of energy discharged per cycle at the rated depth of discharge. This yields units of dollars / kWh / cycles = dollars \* cycles / kWh. Should kWh/n-cycle be considered a total cost versus a normalized cost? While discussion of \$/ (kWh/n-cycle) could be avoided by requiring total costs as inputs rather than normalized costs, normalized costs are more readily available for researchers and for developers in the planning stage.
